

Chunk 1: Project Metadata and Overview

Content: MultiMeet Final Report (May 26, 2026) by Mario Laguna Contreras, Santino Campessi Lojo, and Arnau Donat García. MultiMeet is a mobile social platform for organizing meetups, designed with a focus on community interaction and accessibility. The app offers a fluid experience for discovering, joining, and creating events. This document justifies design decisions regarding usability, accessibility, visual consistency, and the technical stack.

Chunk 2: Usability Strategy - Simplicity

Content: [Overlap: ...visual consistency and tech stack]. Section I: Usability Justification ("Less is More"). MultiMeet reduces cognitive load using standardized visual patterns and digital metaphors. Information is prioritized via maps and event cards, eliminating excessive text. Code Evidence: Use of standard icons from 'lucide-react' (, ,) in TopAppBar.jsx and BottomNav.jsx facilitates immediate understanding without reading labels.

Chunk 3: User Control and Responsive Design

Content: [Overlap: ...understanding without reading labels]. The system is flexible and grants full user control, adapting to any device through robust responsive design. Code Evidence: Extensive use of Tailwind CSS responsive classes (md:grid, lg:flex) in categories/page.jsx and HomeMap.jsx. Practical Example: Navigation adapts from a mobile BottomNav to a desktop sidebar, ensuring the user maintains control regardless of the device hardware.

Chunk 4: Consistency and Error Tolerance

Content: [Overlap: ...regardless of the device]. The app uses a centralized design system via Tailwind CSS and variables in globals.css. Components like EventCard and buttons are systematically reused. Safety & Error Tolerance: Interactive components (EditProfileDialog.jsx) operate via modals, allowing users to cancel or confirm actions without losing context. Real-time validation and loading indicators () reduce perceived latency and inform users during async tasks.

Chunk 5: Accessibility - WCAG Compliance

Content: [Overlap: ...inform users during async tasks]. Section II: Accessibility Justification (WCAG 2.1/2.2). The app ensures visual content is interpretable by assistive technologies. Code Evidence: Systematic use of 'alt' attributes for images (EventCard.jsx). Keyboard Operability: 100% of critical functions are keyboard-operable. Dialogs (SettingsDialog.jsx) use focus traps (useFocusTrap) and close via the Escape key to ensure accessible interaction.

Chunk 6: Advanced Accessibility Features

Content: [Overlap: ...ensure accessible interaction]. Skip Links (WCAG 2.4.1) in ClientLayout.jsx allow users to bypass repetitive headers and jump to main content. High-contrast focus rules are defined in globals.css for keyboard navigation. ARIA & Robustness: Consistent implementation of 'aria-label' for icon-only buttons (NotificationsPopover.jsx) ensures compatibility with modern screen readers like NVDA or VoiceOver. Semantic HTML5 tags are used instead of tables.

Chunk 7: App Navigation and Event Feed

Content: [Overlap: ...used instead of tables]. Navigation is quick and intuitive. Desktop shows a fixed top bar; mobile uses a bottom bar with icons. The Home page features an event feed with tabs: Following, Top City, and Top Global (limited for unauthenticated users). Event cards summarize key data (image, date, location) and link to details. A floating map allows for location-based exploration, and advanced filters refine results by category and date.

Chunk 8: Event Management and User Profiles

Content: [Overlap: ...refine results by category]. Event Details: Displays images, descriptions, map locations, and participant counts. Users can join, share via QR codes, or view "Next Editions". Creation Form: Includes map-based location selection and AI-assisted description generation. Profile Dashboard: Users manage their avatar, bio, and event history (Created, Joined, Past, Upcoming). Public profiles are available for social interaction.

Chunk 9: Tech Stack - Frontend and AI Agents

Content: [Overlap: ...for social interaction]. Tech Stack: Built with Next.js and React for a fast, JavaScript-based application. Development utilized Google Antigravity, an agent-first IDE. Its "Agent Manager" orchestrated multiple AI agents (Gemini 3.5 Flash, Claude Sonnet) to plan, write, and validate complex code. This autonomous assistance accelerated component creation, error resolution, and code refactoring throughout the development lifecycle.

Chunk 10: Tech Stack - Backend and APIs

Content: [Overlap: ...throughout the development cycle]. Database: MongoDB with Mongoose for flexible data storage. Auth: Clerk for secure user management. External APIs: Groq API (Model: llama-3.1-8b-instant) for AI event descriptions, Dropbox for image hosting, QRServer for QR codes, and OpenStreetMap/Nominatim for geocoding and maps. This integration provides a robust, interactive experience. Links: Mockups (Figma), Deployment (Vercel), and GitHub Repository.
